REPORT ON CROP ESTIMATION SURVEYS ON PRINCIPAL FOOD AND NON-FOOD CROPS IN ASSAM 1970-71

1. Introduction

- 1.1 Crop estimation survey on principal food and non-food crops is one of the normal programmes of the Department of Economics and Statistics. The surveys are conducted every year in the different districts of the State, and this report presents the results of the surveys conducted during 1970-71 in the State of Assam (excluding Meghalaya).
- 1.2 The surveys conducted during the year covered the usual principal Kharif and Rabi crops viz. Autumn paddy, Winter paddy, Jute, Rape and Mustard, Potato, Sugarcane and Matikalai. The object of the surveys was to determine the yield rates of the crops and to estimate the productions of those crops for individual districts and for the State as a whole.

2. Coverage.

- The surveys on Autumn paidy and Winter paddy were conducted in all the districts except Mizo district. The coverage was restricted in case of Jute, to the four main Jute growing listricts viz. Goalpara, Kamrup, Darrang and Nowgong. The survey was conducted in all the seven plains districts in case of Potato while in respect of Matikalai the surveys was confined to five plains districts only viz. Goalpara, Kamrup, Darrang, Nowgong and Sibsagar. The surveys on Rape and Mustard and Sugarcane were conducted in all the seven plains districts and also in Mikir and N.S.Hills.
- 2.2 The table below shows the total area under each crop in the State as per final forecast 1970-71 and the area covered by crop estimation surveys during the year under those crops with their percentages to the total area.

Grop	Total area according to final forecast 1970-71 (Hectares)	Area covered by crop estimation surveys (Hectares)	
1	2	3	
1. Autumn paddy	5,27,330	5,27,830	100%
2. Winter paddy	14,46,755	14,14,330	97,75 %
3. Potato	24,570	24,190	98,01%
4. Jute	1,29,355	1,21,230	93.723
5. Sugarcane	32,830	32,230	99 178
5. Rape and Mustare	1 1,37,140	1,37,140	100%
7. Matikalai	49,565	44,490	89 . 74%

3. Design.

- 3.1 The statistical design adopted for the crop estimation surveys is one of the multi-stage stratified random sampling with the Revenue circles or Sub-divisions as the strata. The units in the different stages were taken as follows: villages as the first-stage units, fields growing the crop under survey as second stage units and the experimental plots of specified size in the selected field as the ultimate stage units. In case of Autumn paidy, Winter paidy, potato and Rape and Mustard, the Revenue circles were taken as the strata while in respect of Jute, Sugarcane and Matikalai, the Sub-divisions were considered as the strata in the plains districts. In case of Mikir and Noc.Hills, the district itself was considered as strata.
- 3.2 Within each stratum, a certain number of offlages were selected at random for each crop, the number of selected viles of larger against in proportion to the area under the individual crops in the respective at rates. In case

- 3 -

of Mikir and N.C. Hills the list of villages growing the individual crops constituted the sampling frame for selection of villages.

- In each selected village, two fields growing the crop were selected at random and in each selected field a plot of size 5m x 5m was randomly located for conducting the crop cutting experiments except in case of potato. As the cultivation of potato in the plains districts is in row-system, the size of the experimental plot varied from field to field depending on the spacing between the rows. The experimental plot in case of potato consisted of seven consecutive rows each measuring 5 metres in length. Locating and marking the experimental plots, harvesting and threshing the produce, recording the weight of the produce etc. were the different stages of the experiments.
- The driage experiments in respect of Autumn paddy. Winter paddy, Rape and Mustard and Matikalai were conducted centrally in the Statistical Offices at district/sub-division level under the direct supervision of the Statistical Officers with a view to arrive at an estimate of the percentage recovery of dry grains from the freshly harvested grains. These experiments were confined to a sub-sample of villages only.
- In case of Jute, supplementary operations like retting, extraction of fibres, drying of fibres, recording of final weights etc. were carried out only in 50 p. \sim of the selected villages. For arriving at an estimate of ratio of case to gur, subsequent operations like extraction of juice, preparation of gur etc. were conjected in a limitel number of experiments.
- 3.6 The number of driage experiments planned and actually conducted in different districts for all crops are shown in table 9.1.

4. Organisation.

- The crop estimation surveys were conflucted under the administrative and technical control of the Director of Statistics. Assame in consultation with the Chief Director, National Sample Survey, Govt, of India, All the technical works such as, Planning of the survey including selection of villages, imparting training to the field staff, carrying out analysis of the results etc. were done by the technical staff of the Agricultural Statistics section of the Department of Economics and Statistics, Assame
- The field work of the surveys was carried out by the Field Assistants of the Department of Economics and Statistics, Assam, under the direct control and supervision of the Statistical Officers in the different districts and Sub-divisions. The lists of selected villages for the surveys were supplied to the respective Statistical Officer from the Hendquarters at Shillong well in alvance and the Statistical Officers in the districts and Sub-divisions in their turn, alloted the villages to the Field Assistants for conducting crop estimation surveys. The work load of the field-staff engaged in the different crop estimation surveys in the different districts is shown in table 14.1.

5. Training.

A programme of refresher's training is generally arranged for the benefit of the field staff just before the commencement of different crop estimation surveys every year. During the year under report, necessary training was imparted to the Field Assistants in the technique of field experimentation before starting the actual field work. During the year, the training was organised in three centres viz. at Gauhati, Nowgong and Jorhat in the month of October. The supervisory and field staff of Goalpara, Darrang and Kamrup districts participated in the training organised at Gauhati and those of Gachar Mikir and No.C. Hills and Nowgong at Nowgong centre. The supervisory and field staff of Lakhimpur and Sibsagar districts participated in the training organised at Jorhat. The training was imparted by the officers deputed from Head quarters and the supervisory staff of the National Sample Survey Organisation posted at Shillong. Out of the total strength of 49 Field Assistants 30 had attended the training. Of the rest 19 Field Assistants not attending the training, 3 posts were vacant, 8 Field Assistants were on leave, one was sick, one Field Assistant was under order of transfer at the time of the training.

_ 3 _

The other staff of the districts such as Statistical Officers. Inspector of Statistics, Sub-Inspectors of Statistics, Primary Investigators also attended the training.

The details of training and attendence of the staff are given in table 13.1.

6. Equipments.

All the essential equipments required for successful operations of the field work such as tape, balance, standard weight, string, hessian cloth kit-box etc. were supplied except the pegs which were locally produced by the field staff. The details of equipments supplied to the field staff in the different districts are given in table 12.1.

7. Response.

The district-wise details of number of experiments planned conducted and accepted for analysis with their percentage responses are given in table 1.1. The overall response was found to be satisfactory for all the crops. The percentage responses for the State as a whole were above 96 pucc. for all crops except for Rape and Mustard and Matikalai. In case of Rape and Mustard the response was 92.2 p.c., while the response in case of Matikalai was 85.6 per cent. Cent percent response was achieved in all the districts in case of Autumn paddy. The over all responses in all the districts were above 90 p.c. During the year cent percent response was achieved in Sibsagar district In Mikir and North Cachar Hills and Lakhimpur District also cent percent response was achieved for all the crops except sugarcane in Mikir and North Ills and Potato in Lakhimpur. In case of Winter paddy the over all response, was 98.8 p.c. For this crop cent percent response was achieved in all the districts other than Kamrup, Nowgong and Cachar. The statement of num-response is shown in table 10.1.

8. Supervision.

- The supervision of field work in the different crop estimation 8.1 surveys was entrusted to the District/Sub-divisional supervisory staff. The programme of supervision in pre-assigned villages was arranged in a sub-sample of about 25 p.c. of the sample villages selected randomly in all the in respect of Autumn paddy, Winter pally and Jute surveys for ensuring the quality of the data for the surveys as well as for judging the accuracy of the overall estimates. A total of 376 experiments were planned for such supervision of which only 303 experiments could be supervised by the supervisory staff, the percentage of response being 80.59 percent. Peside these pre-assigned experiments some other experiments were also supervised at harvest stage. In respect of Potato, Sugarcane, Rape and Mustard and Matikalai harvest stage supervision was carried out on 226 experiments or 17.29 percent of the total number of experiments planned for those crops. The details of supervision carried out in the different districts are shown in table 8.1. It will be seen from the table that the over-all supervision at harvest stage was 21.1 percent of the total no, of experiments planned.
- 8.2 In addition to harvest stage supervision, some experiments were supervised by the district supervisory staff at pre-harvest and post-harvest stages. The total no. of experiments supervised at pre-harvest stage was 102 while the no. of experiments supervised at post-harvest-stage was 111 in the State. The particulars of those experiments are presented in table 3.2 of this report.
- 8.3 The supervisory staff of the Directorate of National Sample Survey (Agricultural Statistics Section), Government of India, posted at Shillong carried out independent supervision in case of different crop estimation surveys. The no. of experiments supervised by them at different stages are shown below:

Grops	Pre~ harvest	Harvest	Post-	Driage	Total	Total (excludive)
	2	3	4	5	6	
1. Autumn paidy	17	62	6	-	85	78
2. Winter paidy	46	77	5	-	128	114
3. Jute	13	17	12	6	48	48
4. Potato	19	23	4	•	46	45
5. Rape and Mustard	12	18	26	€ ED	56	52
6. Sugarcane	17	25	13	-	55	52
7. Matikalai	•	1.5	3	•	26	26
Total	132	237	69	6	444	415

In case/supervisions in different crop estimation surveys by the State supervisory staff and the supervisory staff of the National Sample Survey Organisation, posted at Shillong, it was observed that the quality of field work was good and no mistakes in technical aspects of the different crop estimation surveys were noticed. The primary workers were found trained and fully conversant with the technique of crop estimation surveys.

The supervisory staff of Central NSSO, posted at Shillong contacted thirty seven primary workers during Kharif season in seven districts out of 44 primary workers. Eighty four percent of the primary workers contacted were allotted with more than twenty experiments each and 16 page between nine to twenty experiments each. During the Rabi season 1970-71 they contacted 29 primary workers in six districts and noted that all the primary workers were allotted with twenty experiments and above.

It was observed during the supervisions that substitution of survey numbers/fields were done in few cases due to prior harvest of the experimental crops. Information on harvest dates was available at the office of the Statistical Officers about two weeks in advance in respect of all crops except for sugar-name. Harvesting of Sugarcane depends on the availability of the crushing machine and as such no advance intimation of harvest dates could be available like other crops.

9. Procedure of calculation of Average yield of different crops.

9.1 Paidy: In case of paidy, the plot yields recorded in the returns were in terms of grains immediately after thrushing. These plot yields were converted to iry and clean rice in kilogram per hectars. The results of the driage experiments showed that the average moisture contents in the grains was 10.44 percent in case of Autumn padiy and 3.62 percent in case of Winter paidy for the State as a whole (Table 9.2). The dry paidy was then converted to rice by adopting the official conversion factor (62.5 percent) for recovery of rice from paidy.

The stratum average yields were obtained as simple arithmetic mean of the results of all the experiments in the stratum whereas the district average yields were obtained as the weighted average of the stratum average yields, weights being the actual areas under the crop in the respective stratum during the year 1969-70. In case of Mikir and N.C.Hills districts, the district as a whole was considered as a stratum. The average yield for the entire region covered by the survey was obtained as the weighted average of the district averages, weights being the areas under the crop as per final forecast, 1970-71.

9.2 Potato: The stratum average yields were obtained as simple arithmetic mean of the results of all experiments in the stratum expressed in kilogram

per hectare, whereas the listrict and pooled average yields were obtained as the weighted average yields, weights being the actual area in the respective strata during 1969-70 and district areas as per final forecast, 1970-71 respectively.

- 9.3 Sugarcane The stratum average yields and the pooled estimates for the districts and the state were estained in the same procedure as adopted in case of potato. The supplementary operations were carried out in all the 26 experiments planned for obtaining the ratio of gur to cane and the results of the experiments were applied for estimating production in terms of gur. The ratio of the experiments showed that the ratio of gur to cane was 10.51 p.c. (table 9.2).
- 3.4 Rape and Mustari: The experimental yields recorded in the returns were in terms of freshly harvested seeds. Before further analysis the plot yields were corrected for reducted of moisture after driage. The central driage experiments showed an average moisture content of 3.14 percent for the entire region covered by the survey (table 9.2).
- 9.5 Jute The average weight of the "green" harvest for each stratum was obtained as the simple arithmetic mean of the results of the experiments in the stratum. The district and pooled average yields of "green" harvest were obtained as weighted averages, weights being the area under jute in the different sub-distinct during 1969-70 and districts areas as per final forecast 1970-71 respectively.

From the results of the subsequent operations carried out in a sub-sample of 50% of the selected villages, estimates of ratio of dry fibres to "green" weight were worked out for individual districts which are shown below along with the district average of "green" weight. The district estimates of average yields of dry fibres were worked out from the average vields of "green" weight and average percentage ratio of dry to green vields, assuming them to be independent variables.

District	Average vield:, in green weight (Kg./plot.)	Percentage sampling orror.	Average percen- tage ratio of dry to green vield.	Percentage sampling error.
	2		4	5
Goalpara	80	4.14	4.87	3,35
Kamrup	62 [.]	3.69	4.46	9.22
Darrang	50	10.18	5 · 50	3.19
Nowgong	51	6.13	5.47	5,48
Pooled	65	3.43	5.06	2.87

9.6 Matikalai. The plot yields recorded in the returns were in terms of freshly harvested grains. Before carrying out further statistical analysis the results were converted to dry grains. The results of the central driage experiments showed that the average moisture content in the freshly harvested grains was 5.79 p.c. for all the districts taken together (Table 9.2). The district estimates of average yields were obtained as the weighted averages of the stratum averages, weights being the actual areas under the crop in the respective strata during, 1969-70. Similarly the pooled estimate was obtained as the weighted average of the district averages, weights being the district area as per final forecast, 1970-71.

10. Estimates of Average Yieli.

10.1 The following table shows the estimates of average yields of the different crops by districts along with the corresponding nocled estimates for the region covered by the surveys.

						(in Kg./He	ct.)
District	Autumn Pally	Winter Padiy	Potato	Jute	Sugarcane (in terms of cane)	Rape and Mustard	, Matikalai
	1 2	1 3	1 4	5	1 6	1.7	! B,
L. Goalpara	747	877	5645	1.558	45510	406	369

Fey 7 10 d	731	1125	1524	1304	37217	412	347

10.2 The area uniar, production and yields rates of the different crops over a period of five years are presented in tables 3.1(A) to 3.7(A) for their comparisons.

11. Analysis of Variance.

Itsi The results of the analysis of variance of plot yields are given in tables 5.1 to 5.7. The total variation between plot yields was analysed into two component variation viz the variation between villages and variation between fields within village which are given by the corresponding mean squares.

The mean square between fields within village is an estimate of the corresponding true variance while the mean square between villages does not provide an estimate of the corresponding variance. The latter is a function of the two estimated mean squares, the number of villages and the number of fields in the sample, and can readily be computed. Tables 6.1 to 6.7 show the number of villages with varying not of fields required for estimating the average yield at different level of precision in terms of percentage sampling errors.

The formula used for calculating the mean squares and the sampling variance for pally are given in the appendix.

12. Weather and Grop condition.

12.1 Autumn Paily: The weather in general was more or less favourable to this crop barring, of course, Lakhimpur, Darrang and Cachar districts where excessive rainfall hampared the growth of the crop.

There was considerable image to the crop by flooi in some of the listricts at flowering stage. The area under the crop had decreased to a considerable extent in Mikir and N.C.Hills due to draught during the sowing period. However the weather was favourable for the crop in the later stages. The area under the crop was 5,27,330 hectares during 1970-71 against 5,30,335 hectares (excluding Meghalaya) in 1969-70.

The average yields were lower than those of the previous year in most of the districts except in Goalpara, Sibsagar and Mikir and N.C. Hills. Damage by insectpest, were infestation, rice bug and stenborers were negligible during the year. The estimated production of Autumn rice during 1970-71 was 3,79,573 tonnes as against the production of 3,72,441 tonnes (excluding Maghalaya) during 1969-70.

12.2 Winter Paddy: The weather in general was favourable to the emone exact in few districts in the State during the year under report. In some of the listricts draught condition prevailed at the time of transplantation and as a result the areas under cultivation of this crop in those districts had gone foun in comparison to the previous year. The standing crops were affected by flood in some districts. Minor damages by insect pests were reported from a convergions of the State. The area under the crop decreased during the year in Kamrup, Parrang and Nowgong districts in comparison to previous year. The Sotal area during 1970-71 under the crop in the State, which was estimated at 14,45,770 hectares showed an increase of about 0.7 p.c. only over the area of 14,35,431 hectares (excluding Meghalaya) during 1969-70.

The average yields were found to be higher in all the districts except in Coalpara, Lakhimpur and Mikir and N.C.Hills in comparison to the amprage vielts of the previous year.

The total production of Winter rice for the State of estimated at 10,04.317 tomes against 13,35,651 tomes during 1963-70 (excluding Megnalaya) showing an increase of about 15.70 p.c.

The weather was found to be molerately far another to the crop at the time of preparation of land and sowing paration.

The total area under the crop was estimate! 1.22.300 heoteres during 1370-71 against 1.22,012 heoteres texthalling Mr. p. 1.22.300 heroteres during Mr. p. 1.22.300 heroteres during Mr. p. 1.22.300 heroteres texthalling Mr. p. 1.22.300 heroteres texthalling Mr. p. 1.22.300 the primary stage of eneration. But the growth of the empley and the leftly first in almost all the districts and as a result, the yield rates. Therefore, back during the year under report. The production of Jobe faring 1.77. hales of 180 kg, each against the production of 10.87,750 hales of 1969-70 (excluding the production in lare Hills under Magnalage).

- not much firming the weather condition for the propagator result not much firming to during the year. However, in comparison to during the ware areas were trought independent hation in Kamrup, Darrang, Sibbagar, bakhings and Mikir Hills districts. Renords from the districts revealed that the weather during flowering stage was by in some of the districts and this almostly after their the growth of the properties as against the area of 1,34,200 heatares (excluding 1970-71 was 1.77,140 heatares as against the area of 1,34,200 heatares (excluding Meghalaya) in 1959-70. During the year under report, the average yields shown and increase in Jachar, Kamrup, Darrang, Lakhimpur and Mikir Hills districts over those in the provins years. The estimated inplaction during 1970-71 showed an increase of about 11,12 p.c. over the production of 1969-70. The production was estimated at 56,468 tonnes during 1970-71.
- Our field reports from all over the State shows I that the over all weather condition was none too favourable for Sugardane during the year under conort. In Jachar and Kammip districts excessive rainfeld was narrly responsible for the image of the crop. In Mikir Hills dry weather at the prosessive sowing stage was the cause of delay in early operations. However, the weather was favourable for the crop in the subsequent operations in the district. Insect pests acred some damages in certain parts of the State. The estimated area under Sugardane was 32,830 hectares in the State during 1970-71 against 32,850 he dames in 1969-70 (excluding Meghalaya). The average yields recorded a decrease in all the districts except in Mikir and N.C.Hills during the year in a mearing, to those of 1969-70. The over all production of Sugarcane in terms of gir was 1,28,416 tonnes in the State during 1970-71 against 1,61963 tonnes during 1969-70 (excluding Meghalaya).
- The general weather for the crop was more or less favourable to the crop in the after Stages in the State except in Tachar increase. Draughty condition prevailed at the sowing period in some of the districts during the year and as a result the area under the crop recorded a decrease in the last districts as against the area during the previous year. In Sachar district the crop was subjected to damage by excessive rainfall and flood. The extent of damage was estimated at 20 to 50 p.c. in the district. The yield rates in all the districts except in Sachar showed an increase over the previous year. Reports of damage by insect pests were received from Gralagian, 300 many last impur and some parts of Kamrup districts.

The area under the crop was estimated at 24,670 hectares in the State during 1970-71 against 26,250 hectares juring 1969-70.

The estimated production for 1970-71 was 1,11,617 tonnes as against 93,782 tonnes in 1969-70 which meant an increase of about 19.02 p.c.

12.7 Matikalai: The weather was not favourable for the crop at the sowing and post sowing Stages in almost all the districts. The crop was damaged by rainwater in some regions of Kamrup and Nowgong districts and as a result as many as 25 experiments were lost in Kamrup district. The average yields had decreased in Goalpara, Nowgong and Sibsagar districts in comparison to the previous year. The estimated area under the crop had decreased from 56,390 hece tares during 1369-70 to 49,565 hectares in 1970-71. The production of Matikalai was estimated at 17,199 tonnes, in the State during 1970-71 as against 21,086 tonnes during 1969-70.

Mathematical Appendix

Let

- (a) X_{ijk} be the yield from the kth experimental plot of the jth village of the ith circle. Each plot is taken from $(\frac{1}{400})$ th of a hectare.
- (b) \mathbf{x}_{i} be the average yield of the ith circle
- and (c) mi =number of villages in the ith circle.
- 1. The average yield for the ith circle is given by

$$\vec{X}_1 = \sum_{k \in K} x_k / 2mi$$
 (K = 1,2, J= 1,2 m_i

Where sjsk represents summation over villages and fields respectily. The average yield for the district is obtained by weighting the
average yields of circles in proportion to the respective circle
areas under paddy

Where ai - area under paidy in the ith circle and si denotes summation over circles. Similarly the average yield for the districts is obtained from the district average by using the relation.

$$\bar{x} = \sum_{si} - ai \bar{x} / sia_i$$

Where siai area under naddy in the district and \mathbf{s}_i represents the summation over the districts.

Mean yield of dry paddy in kg/hect.= $X \times 400 \times d$ where d is the driage ratio of dry paddy to wet paddy. The weight of cleaned rice is reconed as 62.5 p.c. of dry paddy.

II. The mean square between fields within villages and that between villages are obtained from the plot yields.

For the ith circle the mean square between fields within villages is given by. $F = \frac{1}{2} \left(\frac{1}{2} - \frac{1}{2} \right)^2 / \frac{1}{2}$

based on m₁ degrees of freedom, and the mean square between villages is $E=sj^2$ (xij - x₁)² /(mi - 1)

based on (mi - 1) degrees of freedom.

The mean square between circles in a district is given by $\sin^2(xi-x)^2$ /
L-1 based on L-1 degrees of freedom, L being the number of circles in the district.

The pooled mean squares for the individual districts and for the region as a whole are easily obtained by pooling the circle mean-squares and district mean-squares respectively.

It may be shown that F is andunbiased estimate of the true variance between fields within villages while E is an unbiased estimate of

$$KV + F$$
Where, $K = \frac{1}{m_1 - 1} (sjkj - \frac{sjkj^2}{sjki})$

kj being the number of fields in the jth village,

Since kj = 2 for all j, the above reduces to 2V + F

Hence, an estimate of the true variance between villages is given by $\frac{E-F}{2}$

III. The sampling variance of the estimate of the circle average yield is given by

$$V(xi) = \frac{sjkj^{2}}{(sjkj)^{2}} \quad V + \frac{1}{sjkj} \quad F.$$

$$\frac{(2V + F)}{2m_{1}} \quad as \quad kj = 2 \text{ for all } j$$

$$= \frac{E}{2m_{1}}$$

The sampling variance of the estimate of the average yield for a district is given by

$$V(\bar{x}) = \frac{\sin^2 v(xi)}{(\sin a_i)^2}$$

Similarly the sampling variance of the estimate of average yield for the combined districts is given by

$$V(\bar{x}) = \frac{sa^2 V(\bar{x})}{(sa)^2}$$

The corresponding sampling errors are the square roots of the above variances. The S.E. in kg/hect is obtained by multiplying this root of variance by 400.

IV. It is known that the sampling variance of the estimated average yield for tract is given by

$$\Lambda(x) = \frac{u}{\Lambda} + \frac{u}{\Lambda}$$

Where m is the total number of selected villages

n is the number of fields per village

V is the true variance between villages

F is the true variance between fields.

The number of villages is distributed among the different strata in proportion to the area under the crop.

By using the values of X, V and F for the tract, above formula is used to judge the scale of sampling villages and experimental plots per village for any assigned degree of accuracy of the estimated average yields.
